Abstract:

Relationship between bacteria genetic diversity, sediment organic content, and the ecosystem metabolism of Alpine streams

Bacteria play an important role in the transfer of energy and ecosystem metabolism within freshwater systems. We compared bacteria abundance (DAPI-stained cell counts), relative bacteria genetic diversity (terminal restriction

fragment length polymorphism, T-RFLP, a molecular genetic technique) and sediment organic content (ash-free dry mass: AFDM) in 11 streams of 3 different Alpine catchments during summer 2003. We also related the above parameters, in addition with periphyton biomass and hyporheic respiration, with whole stream estimates of gross primary production (GPP) and ecosystem respiration (ER) in a glacial and non-glacial stream in one of the catchments. Counts of bacteria cells per ml sediment averaged 2×10^6 to 4×10^6 , and were correlated with sediment AFDM for streams in only one of the catchments. The percent organic matter of sediments ranged from 4 to 14% (0.01 to 0.04 g AFDM per ml sediment). Bacteria genetic diversity (based on the presence and absence of terminal sites, T-RFs, from T-RFLP analysis,) showed strong seasonality and differed between glacial- and groundwater-fed streams. In the one catchment, hyporheic respiration averaged 0.0004 and 0.0003 g O₂ h⁻¹ kg sediment⁻¹ and was positively correlated with AFDM ($r^2 = 0.23$). Although ecosystem metabolism displayed a strong seasonality, GPP averaged 4.5 and 8.4, ER 5.4 and 9.9 g O₂ m⁻² d⁻¹ for the two sites, respectively, thus indicating a predominance of heterotrophy in these open-canopied systems.

Key words: T-RFLP, DAPI, hyporheic respiration, open system metabolism, heterotrophy, autotrophy, periphyton

Abstract

We examined macroinvertebrate assemblages of temporary and permanent alpine streams during summer 2003 in the Swiss Alps. Stream types were separated by species richness and abundance even though within stream type variability was high. Temporary streams contained less species and lower individual numbers. Temporary streams could be divided

in 2 groups by duration of surface flow. Streams with short flow periods were dominated by Chironomidae and Oligochaeta, while other temporary streams were dominated solely by Chironomidae. Permanent streams were dominated by Chironomidae and Turbellaria (*Crenobia alpine*) or Chironomidae and EPT taxa. Temporal succession showed no pattern in species richness but showed a replacement of species. Chironomidae assemblages differed between sites with a higher diversity in permanent streams. In the temporary streams, species of the subfamily Orthocladiinae were only found in low abundances. Temporary alpine streams showed similar overall patterns as temporary streams of other regions. Life cycles comparison of the simuliid *Prosimulium latimucro*, which was present at permanent sites as well as temporary, revealed more synchrony and faster development in the temporary site. At one permanent site, the life cycle was fast, whereas the other site showed a lagging period of late instar larvae. High temperatures and low precipitation in summer 2003 lead to extremely dry conditions. Comparison of assemblages with the previous year's data showed a difference in community structure. In 2002 the assemblage was dominated by Chironomidae, while in 2003 *Crenobia alpina* accounted for almost 50% of the assemblages. The assemblage composition of the mid-July 2002 sample resembled those of the 1 July 2003 sample. Life history patterns of *Prosimulium latimucro* showed higher growth in the beginning of the year in 2003. Species composition and life cycle indicate a fast response to unpredictable drought.

Key words: macroinvertebrates, stream, temporary, life history, *Prosimulium latimucro*, Chironomidae, drought

Abstract:

The project is intended to gather baseline ecological information on a number of springs in Val Laschudura and the Swiss National Park. Data generated will be assessed in the framework of geochemical analyses previously completed on the springs. The baseline data will be used to generate future research projects on selected springs, perhaps in collaboration with researchers of springs in other parks throughout Europe.

The research has two facets: one is the longitudinal development in spring metabolism and function, and the other is an assessment of the biodiversity (i.e., macroinvertebrates) of springs and the influence of spring isolation in the distribution of populations. The second part may incorporate a genetic analysis but this is uncertain at present.

Part 1 will examine whole system metabolism in conjunction with measures of primary production and sediment respiration. A number of springs (e.g., 5 different springs) will be assessed at periodic intervals throughout the study period. We also may conduct some measures of bacterial abundances in sediments.

Part 2 will assess the biodiversity of macroinvertebrates in a large number of springs, with samples collected directly near the source (5-10 m below). The data will look for spatial distribution patterns in the assemblages and relate assemblage structure to the physical and chemical properties of the springs. It is possible that a species common to all

springs will be assessed genetically to examine for patterns of isolation and fragmentation.

biodiversity

Abstract:

Although flooding is a primary attribute of most streams and rivers, little information exists on the response of macroinvertebrates during and following flooding. Experimental evidence from disturbance studies suggests that the ramifications on community structure and dynamics can be extreme with both short and long term effects.

A major emphasis on riverine management has been to restore the 'natural' flow regime of rivers downstream of reservoirs. Other aspects of reservoir management have resulted in the actual removal of dams (especially common in the USA). Most dams in Europe and Switzerland, in particular, will likely remain in place for maintaining hydropower production and flow control. Consequently, the most promising avenue for restoring downstream

receiving waters to near natural conditions is to implement flows that emulate expected natural regimes.

Many potential sites for restoring near natural flows below reservoirs have been highly regulated for 10s of years with consequent changes in macroinvertebrate assemblage structure. Its imperative that managers understand the consequences of restoring activities on the ecology of downstream receiving waters.

Objectives:

Compare different types of stream substrata and morphology as areas of refugia for macroinvertebrates during flooding.

Examine the dispersal of macroinvertebrates before, during and after flooding in a pre-defined stream reach.

Subject: Schweizerischer Nationalpark, Sammlungen

Sehr geehrter Herr Robinson

Ich mache im Auftrag der Forschungskommission des Schweizerischen Nationalparks und des Bündner Naturmuseums Recherchen zu Sammlungen aus dem SNP. Sie leiten/leiteten einige Projekte im Fachbereich Hydrologie, die im Nationalpark stattfinden/stattfanden. Allerdings weiss ich nicht, ob während den verschiedenen Projekten auch Aufsammlungen gemacht wurden. Thomas Scheurer meinte, ich solle direkt bei Ihnen nachfragen. Ich habe dazu eine Liste der Projekte zusammengestellt, die mir bekannt sind und zu jedem Projekt mögliche Sammlungen notiert. Ich wäre sehr froh, wenn Sie mir sagen könnten, ob zu den einzelnen Projekten Sammlungsobjekte existieren und wenn ja, wo diese gelagert sind.

Freundliche Grüsse
Marion Schmid
