

A long-time research on alpine water mites

(Acari - Actinedida - Hydrachnella)

C. Bader

The water mites of a rivulet in the Swiss National Park (alt. 2300 m) have been examined on three occasions.

| | 1956 | 1979 | 1981 |
|--------------------|------------------|------------------|------------------|
| | 582 mites | 794 mites | 405 mites |
| | 8 species | 12 species | 11 species |
| Sperchon mutilus | 86 ex. = 14,8% | 110 ex. = 13,9% | 26 ex. = 6,4% |
| Lebertia zschorkei | 155 ex. = 26,6% | 30 ex. = 3,8 % | 4 ex. = 1,0 % |
| Lebertia tuberosa | 269 ex. = 46,2 % | 548 ex. = 69,0 % | 247 ex. = 61,0 % |

The difference in the percentage of the three dominant species are significant statistically.

1970/71 two alpine springs at 2000 m were checked regularly every month during one year for the presence of water mites. Thus it was possible to clarify some problems e.g. the duration of life span, the percentage of males and females (Bader, 1974, 1980).

Some years later, one of these springs was the object of another investigation concerning the composition of water mite-populations: The spring of the "Ova dals Buogls" is situated in a alpine pine forest (*Pinus mugo*) at 2000 m. Temperature (4,40 C) and water level are constant during the whole year.

Since 1977, every October, a big quantity of water moss (12 liters) has been taken from the rivulet about 3 meters below the spring. The moss contains some detritus and has to be washed out with a Thienemann's net, then the remaining material spread out in a water dish. An innumerable quantity of animals (Turbellaria, Crustacea, larvae of Insecta etc.) still remain in the washed-out material. Most of the very small water mite-nymphs remain in the mud. It is not possible to find all of them, and to evaluate this material, but all the water mite "imagines", adults can be discovered. Here are the results of one sample from the period of 1977 - 1989:

Table 1

For the determination of the species it is important to know the stage of development (nymphs and adults) and the sex of the adults. Ny 2: Deutonymphs, N3: Tritonymphs (only for *Sp. violaceus*). The number of the species is variable, but a stock of 10 species has been found in all the 13 years, the remaining 23 species are the so called "visitors".

Table 2

This table is a summary of all samples: 41'041 specimen have been examined! 8 species, present in large quantities, are very interesting for an evaluation.

The classification (in 4 classes) of dominance after Schatz ('1979) can be used:

| | |
|-------------|----------|
| eudominant | > 10 % |
| dominant | 5 - 10 % |
| recedent | 1 - 5 % |
| subrecedent | < 1 % |

Table 3

The distribution of the 8 important rheophilous species has changed during the 13 years:

| | |
|-------------------------------|------------------------|
| <i>Sperchon vioaceus</i> | eudominant |
| <i>Lebertia zschorkei</i> | eudominant |
| <i>Sperchon thienemanni</i> | eudominant - dominant |
| <i>Feltria setigera</i> | eudominant - recedent |
| <i>Lebertia tuberosa</i> | dominant - recedent |
| <i>Lebertia robusta</i> | dominant - recedent |
| <i>Atractides glandulosus</i> | dominant - subrecedent |
| <i>Sperchon mutillus</i> | recedent - subrecedent |

There are only 2 species which are constantly dominant during 13 years:

1. *Sperchon (Scuto) vioaceus* Walter, 1914.
This species has been found not only in the Alps (700 - 2500 m), but also in the Pyrenees and in Czechoslovakia. The vividly red mite lives exclusively in the moss of the springs and rivulets. It is an excellent indicator of unpolluted water. *Sp. vioaceus* is closely related with *Sp. denticulatus* Koenike, 1895, which is a wide spread species in the plains and mountains (up to 1000 m) all over Europe (Bader, 1974)

2. *Lebertia (Pseudo) zsnochkei* (Koenike, 1902)
Like *Sp. violaceus* this is a typically alpine form, found in the Alps (600 - 2460 m), in Germany (850 m), Czechoslovakia, Yugoslavia and Spain (900 m).
3. *Sperchon (s.str.) thienemanni* Koenike, 1907
This species has also been described formerly as *Sperchon (s.str.) glandulosus* (Koenike, 1886), but the author could separate these two species (Bader, 1974): *Sp. thienemanni* is a typically alpine form (up to 2460 m), whereas the other species has been reported only from the European plains and mountains up to 1000 m.
4. *Feltria (s.str.) setigera* Koenike, 1986 has several synonyms. It is not possible to identify all the indicated locations, but the species is certainly an alpine form.
5. *Lebertia (Pseudo) tuberosa* Thor, 1914 has been found in the Alps (900 - 2500 m), in Central Europe (Germany and Czechoslovakia), in the Pyrenees, in Hungary, Yugoslavia, Romania and Russia (Kaukasus). It is a rheophilous form.
6. *Lebertia (Hexa) robusta* Walter, 1922. The locations of this alpine rheophilous species are limited. It has only been found in the Alps (Switzerland, Italy, up to 2000 m).
7. *Attractides glandulosus* (Walter, 1918) has been reported at first from the Swiss plains (400 m) and later discovered in Austria (800 m), Germany, France (Midi) and Spain.
8. *Sperchon (s.str.) mutillus* Koenike, 1895 lives in the middle regions of the alpine rivers and can migrate upwards the springs. Locations reported also from Germany, Czechoslovakia, Hungary, Yugoslavia and Romania.
9. *Panisus nichaeli* Koenike, 1986 and
10. *Hygrobates (Rivobates) norvegicus* (Thor, 1897). These two species have been found in minimal quantities during all the 13 years. They usually are inhabitants of springs with low temperatures, some specimen of these species have drifted downwards.

With one exception the rest of the 33 species are "visitors". They accidentally immigrated the locality of the Ova dals

Buogls from other biotops.

32. *Aturus (s.str.) scaber* Kramer, 1875 is a rheophilous species, wide spread in cold rivulets all over Europe, it has never been found in the Swiss Alps. The author found one unique male of this species. The nearest locality where the species has been found is situated in the Dolomit-Mountains (Italy, 1700 m) in a distance of about 100 km from the Oval dals Buogls.

The diagrams: At the moment it is not possible to recognize significant regularities or trends in the 8 diagrams. A cycle of 10 - 12 years could be supposed (sun spot cycle?). This research will be continued in the next years!
