1. Abstract

Grasslands are ubiquitous ecosystems that cover almost 41% of the Earth's terrestrial landscape. These ecosystems support large communities of vertebrate and invertebrate herbivores. An important role within grassland ecosystems falls to the Orthoptera as they can consume large amounts of biomass. The occurrence of Orthoptera within grassland systems is strongly affected by habitat diversity and vegetation structure, which in turn can be shaped by large herbivores. Indeed, several studies focused on the impact of livestock on Orthoptera, but little is known about how wild ungulates affect the abundance and diversity of Orthoptera in grassland ecosystems.

In the Swiss National Park (SNP) red deer (*Cervus elaphus* L.) and chamois (*Rupicapra rupicapra* L.) strongly influence the vegetation structure of subalpine grasslands and create a distinct vegetation pattern: short-grass (SG) is found on former cattle pastures where large herbivores graze intensively today, tall-grass (TG) in areas that were traditionally used as hay meadows that are subject to less large herbivore grazing. Consequently, our main goal was to determine how vegetation type (SG or TG), as well as how vegetation structure and habitat diversity, affected Orthoptera abundance and species diversity. Vegetation structure and habitat diversity was measured on 36 transects located on 6 grasslands within the park. In each grassland half of the transects were located in SG, half in TG vegetation. On the same transects Orthoptera were counted in open quadrates and were caught by sweep-netting. Caught Orthoptera individuals were identified to species level.

In total we found nine Orthoptera species, and caught 0.5 individuals per square meter on average. Our results showed that Orthoptera abundance and diversity were not influenced by vegetation type, i.e., no difference was found between Orthoptera numbers in SG and in TG vegetation. We can think of several reasons for this phenomenon: first, we might observe a natural grassland ecosystem in which one player has adapted to the presence of the others; secondly, Swiss mountain Orthoptera species might react differently to grazing than those in other grassland ecosystems; thirdly, dung removal might have erased a potential effect. Orthoptera abundance was influenced by vegetation structure similar to other studies. The observed increased abundance in higher vegetation probably was due to a favourable microclimate and shelter from predators. Also Orthoptera species diversity increased with higher vegetation. Orthoptera abundance increased with higher proportion of grasses but decreased with habitat diversity, which was inversely linked to grass proportion. Similar to Orthoptera abundance, also species richness decreased with habitat diversity. Orthoptera species composition at the different locations differed considerably and could be explained by vegetation structure, habitat diversity, altitude and distance and is roughly the same as some eighty years ago.

2. Introduction

Grasslands are defined as habitats dominated by grasses (Gibson, 2009). Beside grasses and forbs dwarf shrubs, dicotyledons, lichens or mosses may also occur (Coupland, 1979). These ecosystems cover approximately 40.5% of the Earth's terrestrial landscape (White *et al.*, 2000), and support large populations of vertebrate and invertebrate herbivores. Orthoptera - containing the two suborders Ensifera (crickets and bush crickets) and Caelifera (grasshoppers) - are important components of grassland ecosystems as they consume approximately 0.3 – 8.0 % of net primary production (Köhler *et al.*, 1987 and references within). They are wasteful feeders as they clip the grasses in the middle and then feed on the lower part only (Ingrisch & Köhler, 1998). *Chorthippus parallelus* is, for example, known to consume 2% of net primary production and waste a further 8% (Ingrisch & Köhler, 1998). In high altitude ecosystems, Orthoptera herbivory is found to have an even greater impact than in the lowlands – with Orthoptera removing 19 – 30 % of the aboveground phanerogam biomass (Blumer & Diemer, 1996). Orthoptera species are not only important as herbivores for the grassland ecosystem but also as a prey source. Predators are invertebrates (insects, spiders, etc.) and birds (Dempster, 1963).

Arthropod species diversity is strongly influenced by habitat heterogeneity with habitat heterogeneity being the most important predictor of arthropod species richness (Báldi, 2008). A diverse habitat consists of many microhabitats, which can fulfil the needs of different species and different life stages. Orthoptera species will find a variety of food sources, shelter, oviparity and sun basking sites and appropriate humidity in a diverse habitat (Curry, 1994; Ingrisch & Köhler, 1998). Consequently, grasshoppers are more abundant in certain habitats than in others. In addition to habitat diversity, vegetation structure also has a large influence on grasshopper distribution (Clark, 1948; Gardiner *et al.*, 2002). For example, Gardiner *et al.* (2002), who investigated the relationship between sward height and the density of three grasshopper species (*Chorthippus albomarginatus*, *Chorthippus brunneus* and *Chorthippus parallelus*), found highest grasshopper abundance at an intermediate sward height.

Habitat diversity and variability is created by large mammalian herbivores in many grassland ecosystems (Adler *et al.*, 2001; Frank, 2006). Consequently, these animals directly (through forage competition) or indirectly (by altering habitat heterogeneity and vegetation structure) influence the abundance and diversity of Orthoptera inhabiting the same ecosystem (Suominen & Danell, 2006). However, most studies that investigated the impact of large herbivores on the Orthoptera communities considered livestock (e.g. Holmes *et al.*, 1979; Jepson-Innes & Bock, 1989; Welch *et al.*, 1991; O'Neill *et al.*, 2003), and little is known about the interactions between non-domestic large mammals and Orthoptera. We are aware of only two studies conducted in natural grasslands. Grasshopper densities were reported to increase with bison grazing (Joern, 2004). In contrast, decreasing Orthoptera densities were reported under increasing grazing pressure by wild African ungulates (Samways & Kreuzinger, 2001). Given the importance Orthoptera play in grassland ecosystems, this lack of research is surprising. Consequently,

the aim of our study was to gain a better understanding on how large herbivores influence the abundance and diversity of Orthoptera in natural grassland ecosystems. We assessed the impact of wild ungulates on Orthoptera abundance and species diversity in the Swiss National Park (SNP).

Red deer and chamois create distinct vegetation patterns in the subalpine grassland ecosystems of the park: Short-grass (SG) is found where they graze intensively, while tall-grass (TG) is found in areas subject to less large herbivore grazing (Schütz *et al.*, 2003, 2006). Thus, we assessed Orthoptera abundance and diversity in these two vegetation types. We also measured vegetation structure and habitat diversity within these vegetation types and assessed whether these parameters have an effect on Orthoptera abundance and species diversity.

3. Methods

3.1 Study area

The study was carried out in the Swiss National Park, which is located in south-eastern Switzerland. Between 1960 and 2009 the park's weather station at Buffalora (1980 m a.s.l.) recorded mean annual precipitation of 871 ± 156 mm and mean annual temperature of 0.6 ± 0.6 °C. The park covers an area of 170 km^2, of which three square kilometres are subalpine grasslands. The elevations within the park range from 1350 to 3170 m a.s.l. (Risch *et al.*, 2008).

Our study sites were associated with a bigger study focusing on the impact of various herbivores on grassland ecosystem patterns and processes on subalpine grasslands. They were located on Alp Stabelchod (sites 1-4), Stabelchod Dadaint (5 & 6), Margunet (7 & 8), Val dal Botsch (9 & 10), Alp Grimmels (11-14) and Alp Mingèr (15-18; Figure 1), and their elevations ranged from 1975 m a.s.l. to 2300 m a.s.l.. Sites with uneven numbers were established on heavily grazed SG vegetation, those with even numbers on TG vegetation. SG vegetation was dominated by red fescue (*Festuca rubra* L.), perennial quaking grass (*Briza media* L.), and milfoil (*Achillea millefolium* L.), while TG vegetation was dominated by evergreen sedge (*Carex sempervirens* Vill.), mat-grass (*Nardus stricta* L.), and Bellard's Kobresia (*Elyna myosuroides* (Vill.) Fritsch) (Risch *et al.*, 2008). At each study site we established two 4m wide x 25m long transects to assess the Orthoptera abundance and diversity.

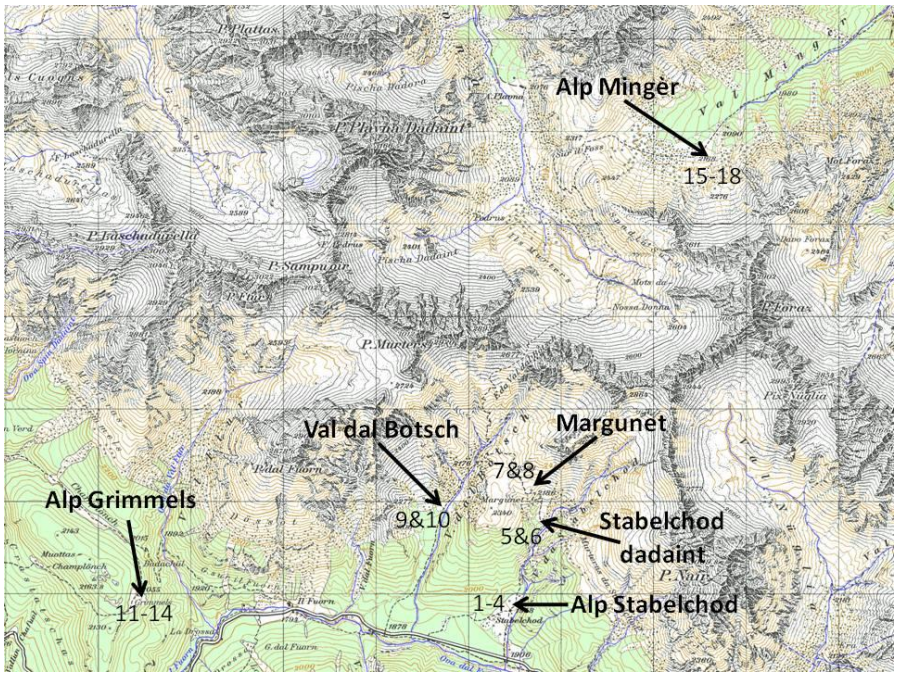

Figure 1: Overview of the six sites in the Swiss National Park. Map: Swiss Map 50. Numbers refer to sites.

3.2 Orthoptera abundance and diversity

Orthoptera abundance and species composition was assessed by counting, catching and by recording Orthoptera stridulation sounds. Counting and catching took place in different weeks to assure that one method did not influence the other.

The method used for counting Orthoptera was adapted from Gardiner *et al.* (2002). Orthoptera were counted in five fixed open quadrate plots ($0.25m^2$) located at 5, 10, 15, 20 and 25 m of each transect. The counts were conducted every two weeks from mid-June to the end of August 2010. The fixed plots were approached simultaneously by two people and the number of jumping Orthoptera individuals emerging from within the plots counted. In addition, we searched for hidden individuals by sweeping through the vegetation by hand. All the counts were extrapolated to the number of individuals counted per m^2.

Orthoptera were also caught four times over the course of six weeks between the beginning of August and mid-September 2010. During one week all transects were sampled. For this purpose, we divided the transects into 25 one meter segments, six of which were available per catching session (Figure 2). Five out of six segments per transect were sampled with sweep nets (30cm diameter; Forestry suppliers Inc. Jackson, MS, USA) on dry days between 09:20 and 17:00. For this purpose, two persons positioned themselves at opposite ends of a segment and then started sweeping while walking towards the centre simultaneously. One person swiped the net slightly faster than the other one in order to catch rapid and slow dispersal species (Foster & Reuter, 1996). All adult Orthoptera were identified to the species level following Baur *et al.* (2006), larvae were counted but not identified and all individuals were released in the same segment as they were caught. All the catches were extrapolated to the number of individuals caught per m^2.

For Orthoptera abundance analysis larvae were included. In addition to catching Orthoptera, we also determined the presence of Orthoptera by recording stridulation sounds. These records served as a control to check the species list obtained from the catches. Records were taken with an ultrasonic detector (Magenta Bat4, Magenta Electronics Ltd, Burton-on-Trent, GB) and a voice recorder (Maxfield MAX G-Flash Metal, Maxfield GmbH, Düsseldorf, Germany) between mid-August and mid-September between 10:35 and 15:25 on sunny, dry days with temperatures between 9°C and 20°C and with light wind only. One record was taken over about 15 minutes and 100m distance. When recording Orthoptera sounds, individuals of a large area can be heard. Thus, we collected one record for all transects that were within 100m reach. For each group of transects up to six records were taken. Records were analyzed with the help of the program Audacity 1.2.6. and Roesti & Keist (2009).

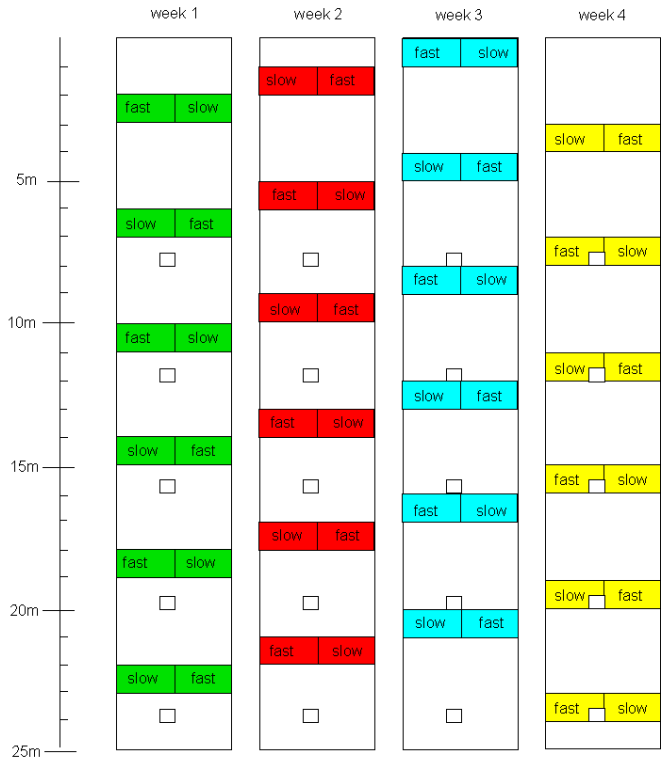

Figure 2: In each of the four weeks different parts of the transect were used for Orthoptera catching. Small white quadrates indicate where Orthoptera counting took place. Counting was finished before the third catching week.

Using Orthoptera catches m^{-2} we were able to calculate Orthoptera abundance and species diversity. The latter term was expressed as species richness ($S_{Orthoptera}$) and as Shannon Index ($H'_{Orthoptera}$). Species richness (S) equals the total number of species per square meter. Shannon Index (H') accounts for species richness and evenness and is calculated based on the relative abundance p of species i (Magurran, 1988; Equation 1). A high Shannon Index stands for high species richness and evenness:

(Equation 1) $$H' = -\sum_i (pi * ln(pi)) \qquad pi = \frac{ni}{N}$$

where *pi* refers to the relative abundance of species *i*.

3.3 Ecosystem parameters influencing Orthoptera abundance and diversity

We assessed the effect of vegetation type, vegetation height and habitat diversity on Orthoptera abundance and diversity. Vegetation type was given by the experimental design. Vegetation structure was measured for each 25m transect. For this purpose we divided the four meter width of a transect into three equal parts and placed a 25m long measuring tape in the centre of each part. We then recorded the vegetation height next to the tape at 0.5m intervals (=3 x 50 records per transect). Habitat diversity was expressed as diversity in vegetation cover, which we assessed at 0.5 m intervals along the tape. Thereby we distinguished between grasses, herbs, mosses & lichens, rocks, bare soil, woody plants, ant hills or wood. These values were then used to calculate habitat diversity ($H'_{Habitat}$) using the Shannon index (Equation 1; *pi* = proportion of vegetation cover *i*).

According to Heidorn & Joern (1987), grasshoppers prefer grasses with high nitrogen content. We therefore used plant nitrogen data from 2009 that was collected on plots in immediate proximity of the transects as a part of the larger exclosure project. Plant nitrogen concentration was analyzed by dry combustion on a TruSpec SN analyzer at 950°C (Leco Corp., St. Joseph, MI, USA) from plant material harvested in September 2009 that was dried at 65°C, and ground through a 0.5 millimetre sieve.

3.4 Distribution of Orthoptera species in the Swiss National Park

Since we were catching Orthoptera on grasslands located in different parts of the SNP, we tested which grasslands had most similar Orthoptera species compositions and which factors influenced them. Orthoptera catches of two neighbouring transects which belonged to the same site were summed.

3.5 Statistical analyses

Transects from site 16 were excluded from the $S_{Orthoptera}$ and $H'_{Orthoptera}$ calculations as no Orthoptera had been caught at any time of sampling. For calculating $H'_{Orthoptera}$, Orthoptera catches of five replicates of each transect were summed in order to minimize zero values. All data was tested for normality and Orthoptera catches m^{-2} were square root transformed SQRT(Orthoptera catches m^{-2} + 0.5) according to Sokal & Rohlf (1995). To assess how vegetation height and habitat diversity affected Orthoptera abundance and diversity we used linear regression analyses. Thereby, Orthoptera catches m^{-2}, $S_{Orthoptera}$ and $H'_{Orthoptera}$ were the dependent variables and vegetation height and $H'_{Habitat}$ were the independent variables, respectively. The effect of vegetation type on Orthoptera abundance and diversity was tested with one-way-ANOVA. Further linear regression analyses were conducted to assess how the different vegetation cover types affected Orthoptera abundance and diversity, and how nitrogen concentration affected Orthoptera abundance. Vegetation cover variables and plant nitrogen concentration were the independent variables and Orthoptera catches m^{-2}, $S_{Orthoptera}$ and $H'_{Orthoptera}$ the dependent variables, respectively. All these statistical analyses were conducted with "IBM SPSS Statistics 19" (SPSS Inc, Chicago, USA).

A principal coordinates analysis (Wildi, 2010) was performed to assess Orthoptera species composition in different areas of the SNP. Orthoptera catches were square root transformed and species vectors were normalized. We measured similarity in Orthoptera species composition between locations with the following equation (Wildi & Orlòci, 1996):

(Equation 2)
$$S_{x,y} = \frac{\sum x_i y_i}{\sum x_i^2 + \sum y_i^2 - \sum x_i y_i} \; (i = 1, \ldots, n)$$

X_i and y_i represent how many times species i occurred in locations x and y, and n is the number of Orthoptera species.

4. Results

4.1 Orthoptera abundance and diversity

During our sampling sessions we counted 715 and caught 1388 Orthoptera individuals, 882 of which were adults. We found nine different species in total: Roesel's bush-cricket *Metrioptera roeselii* (Hgb), which belongs to the taxonomic suborder of Ensifera, and *Bohemanella frigida* (Boh.), *Chorthippus biguttulus* (L.), *Chorthippus parallelus* (Zett.), *Gomphocerippus rufus* (L.), *Gomphocerus sibiricus* (L.), *Omocestus viridulus* (L.), *Podisma pedestris* (L.) and *Tetrix bipunctata* (L.), which all belong to the taxonomic suborder Caelifera (grasshoppers). Species determination check with stridulation sounds gave good results, as in most cases the species lists for Orthoptera catches and Orthoptera stridulation sound records corresponded perfectly (Appendix A).

The maximum number of individuals counted on a transect was 18.4 per square meter (average 2.6 m^{-2}), whilst the maximum number of individuals caught per square meter was 2.4 (average 0.5 m^{-2}). Orthoptera catches and Orthoptera counts per square meter were highly correlated (R^2=0.694, df=34, F=77.002, $p < 0.001$; Figure 3). Thus, we used Orthoptera catches per square meter as an estimate of Orthoptera abundance. $S_{Orthoptera}$ varied between 0.00 and 0.50 per transect and $H'_{Orthoptera}$ between 0.00 and 1.28.

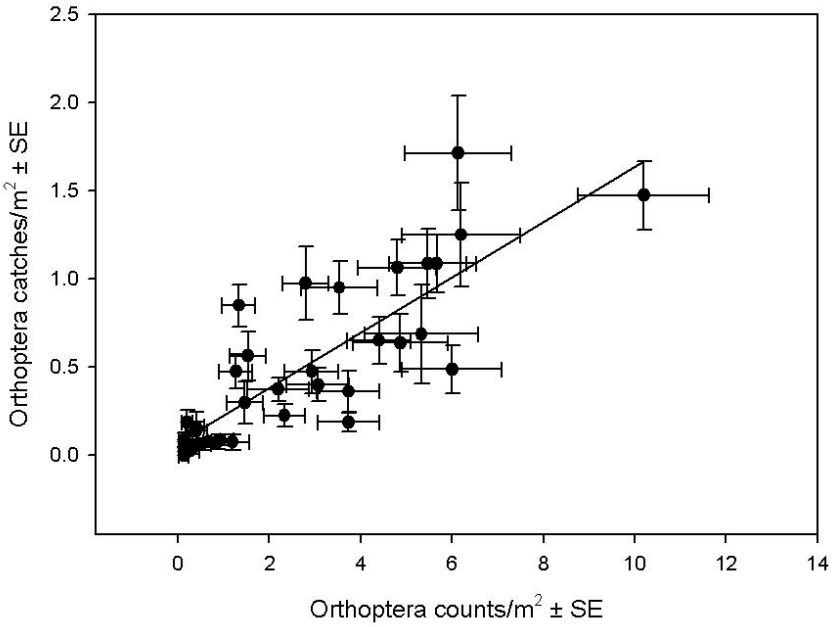

Figure 3: Orthoptera catches m^{-2} were linearly correlated with Orthoptera counts m^{-2}.

4.2 Ecosystem parameters influencing Orthoptera abundance and diversity

When comparing Orthoptera catches m^{-2} for SG and TG vegetation no significant difference was detected (df=34, F=2.548, p = 0.120), thus, differences in grazing patterns of red deer and chamois did not influence Orthoptera catches. The grazing pattern also had no significant influence on Orthoptera species diversity ($S_{Orthoptera}$: df=32, F=3.83, p=0.059; $H'_{Orthoptera}$: df=32, F=1.778, p=0.192).

In contrast, both Orthoptera abundance (R^2=0.357, df=34, F=18.897, p < 0.001; Figure 4) and Orthoptera species diversity ($S_{Orthoptera}$: R^2=0.48, df=32, F=29.575, p < 0.001; $H'_{Orthoptera}$: R^2=0.227, df=32, F=9.380, p=0.004) were correlated with vegetation height (ranging from 3.39 cm to 16.09 cm per transect), all values increasing with increasing vegetation height.

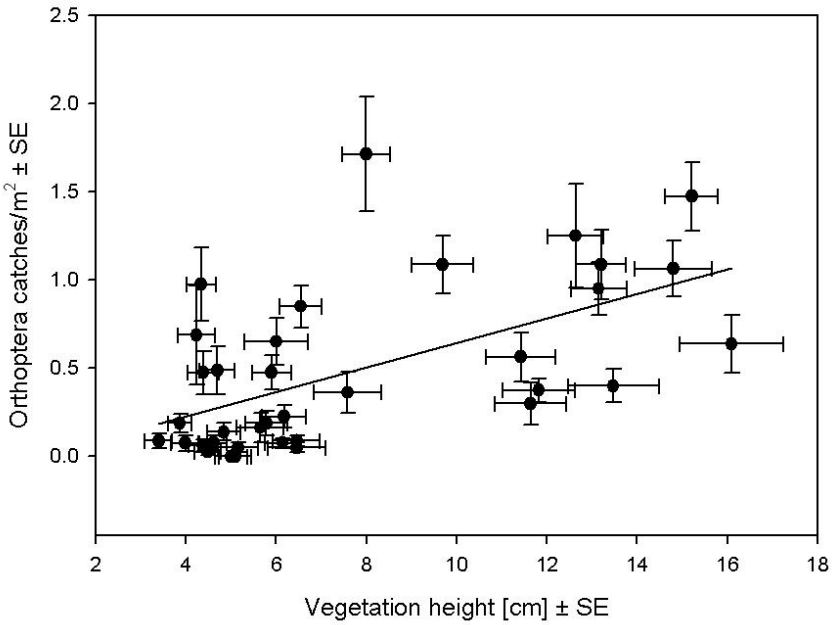

Figure 4: Orthoptera catches m^{-2} were linearly correlated with vegetation height.

Orthoptera abundance (Orthoptera catches m^{-2}; R^2=0.305, df=34, F=14.927, p < 0.001; Figure 5) was negatively linearly related to habitat diversity ($H'_{Habitat}$). $H'_{Habitat}$ was negatively linearly correlated with $S_{Orthoptera}$ (R^2=0.159, df=32, F=6.042, p=0.020), but no correlation was found with $H'_{Orthoptera}$ (R^2=0.009, df=32, F=0.304, p=0.585).

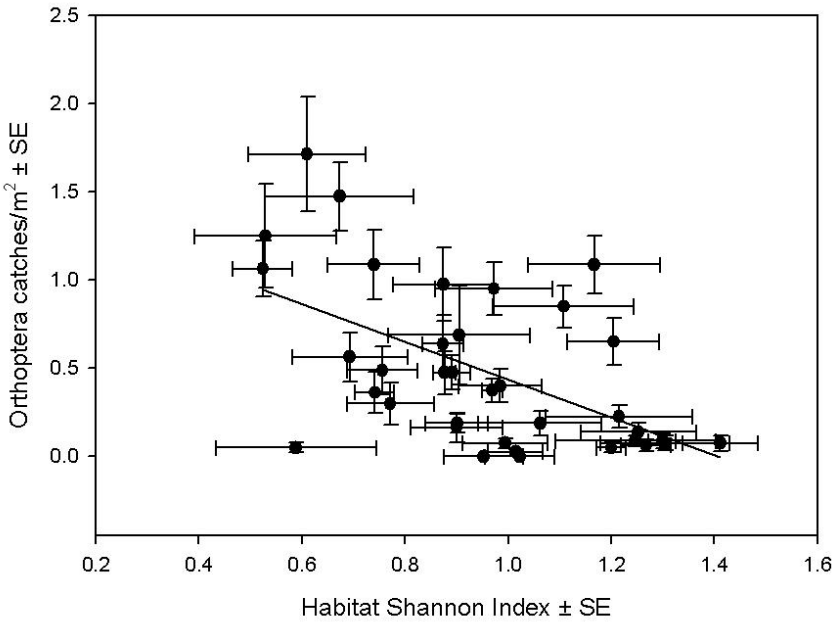

Figure 5: Orthoptera catches m^{-2} were negatively linearly correlated with $H'_{Habitat}$.

The vegetation cover variables measured that correlated with Orthoptera abundance (Orthoptera catches m^{-2}) were the proportion of grasses and the proportion of herbs. The proportion of grass was positively correlated with Orthoptera catches m^{-2} (R^2=0.222, df=34, F=9.703, p = 0.004), while herbs were negatively correlated with Orthoptera catches m^{-2} (R^2=0.116, df=34, F=4.443, p=0.042). $H'_{Habitat}$ was lower when the proportion of grasses was higher. No relationship between any of the parameters measured was found for $S_{Orthoptera}$ and $H'_{Orthoptera}$.

The nitrogen concentration of SG vegetation was significantly higher than the one of TG vegetation (df=34, F=13.667, p=0.001). In SG, plant nitrogen concentration was correlated with Orthoptera abundance (R^2=0.538, df=16, F=18.624, p=0.001), whereas no correlation was found for the TG vegetation (R^2=0.007, df=16, F=0.109, p=0.746). Plant nitrogen had no influence on Orthoptera diversity ($S_{Orthoptera}$: R^2=0.025, df=32, F=0.837, p=0.367; $H'_{Orthoptera}$: R^2=0.018, df=32, F=0.577, p=0.453).

4.3 Distribution of Orthoptera species in the Swiss National Park

Orthoptera species composition differed considerably within the SNP (Figure 7). Multivariate analyses showed that three distinct aggregation groups could be observed (Figure 6). In the lower right corner, sites 1-6 are located, which represent all transects located on Alp Stabelchod and Stabelchod Dadaint. Species *Chorthippus parallelus* and *Metrioptera roeselii* gave distinction to the communities in these areas characterized by low $H'_{Habitat}$. In the upper left corner, sites 11-13 are aggregated, all of those were located on Alp Grimmels with *Chorthippus biguttulus* as a characteristic species. They were separated from other locations in distance (X-Coordinate). In the bottom left corner, sites 7-10 and 15, 17 and 18 were located. Those sites were located on Margunet, Val dal Botsch and on Alp Mingèr. *Gompocerus sibiricus* occurred in these places and they were characterized by low vegetation height and high

altitude. Site 14, also located on Alp Grimmels, was the only site not clearly belonging to one of the three groups.

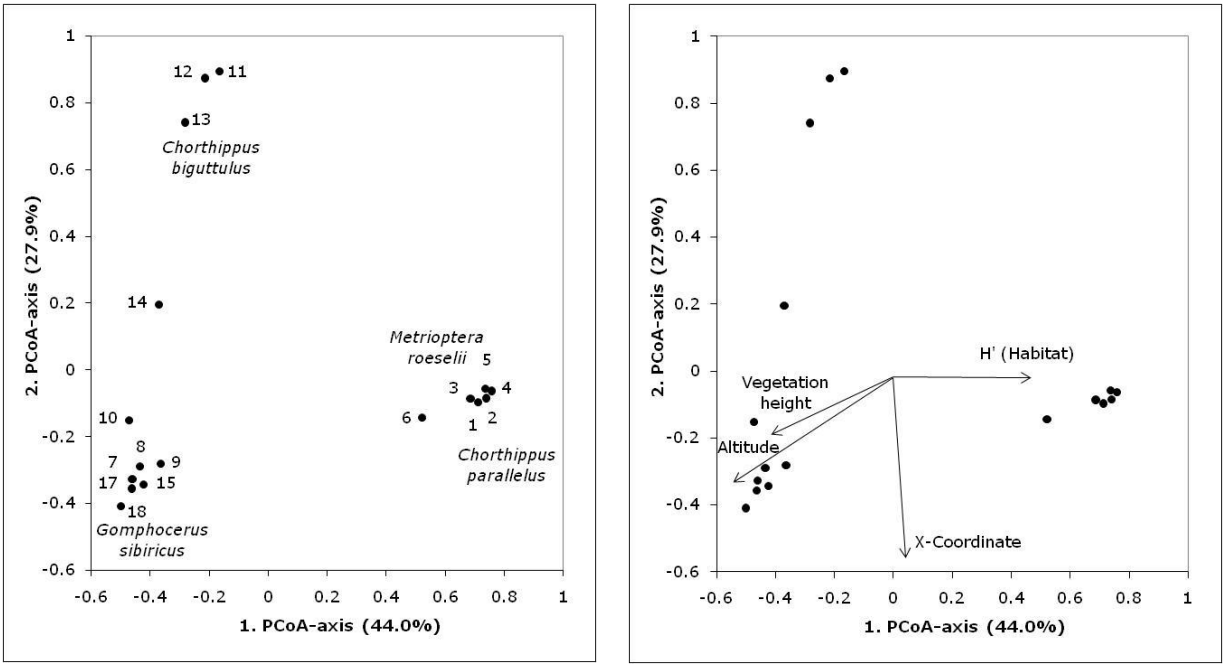

Figure 6: Sites are aggregated according to Orthoptera species composition. Numbers stand for the site number.

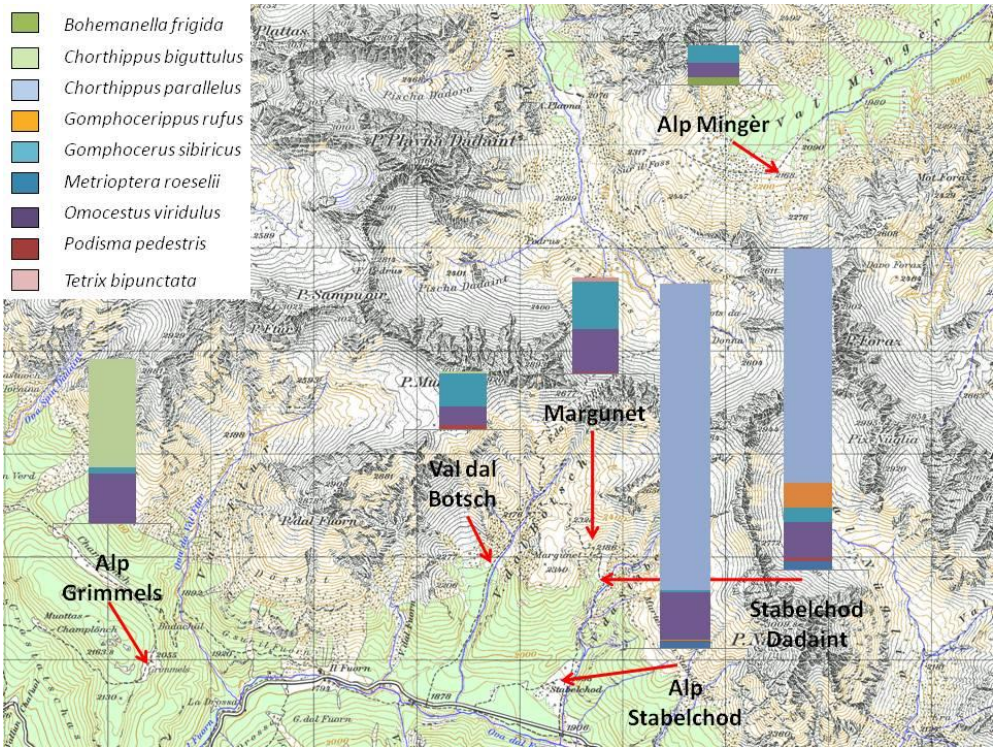

Figure 7: The species composition of all six locations visualized as column graphs. Size of column bars corresponds to the relative number of caught Orthoptera per location. Background map: Swiss Map 50.

5. Discussion

5.1 Orthoptera abundance and diversity

The average Orthoptera abundance (0.5 catches per square meter) found in the SNP is similar to that found in other studies (Jepson-Innes & Bock, 1989; Welch *et al.*, 1991; Gardiner *et al.*, 2002; O'Neill *et al.*, 2003), ranging from 0.0 to 3.4 individuals per square meter. O'Neill *et al.* (2003) for example, had an average abundance of 0.1 grasshoppers per square meter and sweep net sample. Unfortunately, we were not able to compare Orthoptera species richness to other studies as they did not relate their species numbers to absolute areas (e.g. Samways & Kreuzinger, 2001), or did not focus on species richness at all (e.g. O'Neill, 2003). As the SNP is located at high altitude, Orthoptera species richness is expected to be relatively low (Wettstein & Schmid, 1999).

5.2 Ecosystem parameters influencing Orthoptera abundance and diversity

Our results suggest that wild ungulates do not directly influence the Orthoptera communities in the SNP since Orthoptera abundance and species diversity did not differ between the two vegetation types. The two studies we found in the literature that assessed how wild ungulate grazing affects Orthoptera abundance found contrasting results to our study. Joern (2004) reported higher Orthoptera numbers under bison grazed conditions in the Konza tall-grass prairie in Kansas (USA). He explained his findings with increased food quality and altered habitat structure in grazed vegetation. In contrast, Samways & Kreuzinger (2001) found lower abundance of Orthoptera with increasing grazing pressure within grasslands of a game park in South Africa. Their explanation for the decreased invertebrate density under wild ungulate grazing was a change in habitat structure. Higher (Holmes *et al.*, 1979) or lower (Jepson-Innes & Bock, 1989; Welch *et al.*, 1991; O'Neill *et al.*, 2003) overall Orthoptera abundances were also found with livestock grazing. Also these authors explained their findings by altered food quality and microhabitat with grazing. Interestingly, O'Neill *et al.* (2003) used an experimental livestock density of 10.8 ind./km^2 - which is comparable to the density of red deer in SNP (personal communication SNP) – but found lower Orthoptera abundance when the large herbivores were present. We can think of several reasons that could explain this difference in results:

1) Our study was conducted in a natural grassland ecosystem, in which Orthoptera, red deer and chamois have coexisted in situ for dozens of years and therefore are adapted to the presence of the others. In contrast, livestock-grazing was simulated over a certain period in the study of O'Neill *et al.* (2003).

2) It was reported that different species react differently to grazing (Holmes *et al.*, 1979; Jepson-Innes & Bock, 1989; O'Neill *et al.*, 2003). The Orthoptera species occurring in the SNP are completely distinct to the ones in studies conducted in Africa (Samways & Kreuzinger, 2001) or North America (Holmes *et al.*,

1979; Jepson-Innes & Bock, 1989; Welch *et al.*, 1991; O'Neill *et al.*, 2003) with no pest species present in the Swiss mountains.

3) Ungulate dung, which otherwise could have attracted Orthoptera, had been removed from the transects (dung counts for herbivore exclosure project). This might have influenced Orthoptera distribution, as grasshoppers (*Chorthippus parallelus*) have frequently been observed on dung heaps (personal observation; Figure 8).

Figure 8: *Chorthippus parallelus* individuals sitting on dung heaps. (Alp Stabelchod, 30.08.2010)

As reported in other studies (Clark, 1948; Morris, 2000; Gardiner *et al.*, 2002), vegetation structure had a large influence on grasshopper distribution in the SNP as we caught significantly more Orthoptera individuals in taller vegetation. One reason for these findings might be related to more favourable microclimatic conditions (humidity, temperature) found in taller vegetation. Tall vegetation is not so readily warmed by the sun nor cooled by free circulating air (Clark, 1948), so the microclimate in tall vegetation is more stable than that of shorter vegetation. This, in turn, would indicate the patches with taller vegetation are actively selected by the insects (Ingrisch & Köhler, 1998). A second reason might be that Orthoptera profit from the cover from predators in the tall grass (Grayson & Hassall, 1985). We found that vegetation structure also significantly influenced Orthoptera species diversity ($S_{Orthoptera}$ and $H'_{Orthoptera}$), which increased with higher vegetation. Also, Morris (2000) found an increased overall arthropod species richness with higher vegetation which he explained by the increased food availability.

Orthoptera abundance was negatively correlated with habitat diversity. This might be surprising on first sight but with a closer look at habitat diversity it becomes clearer. Proportion of grasses was negatively correlated with habitat diversity and Orthoptera abundance was positively related to the proportion of grasses. Thus, in the SNP more Orthoptera are found in a non-diverse habitat as such a habitat

containing a lot of grass. Since all the species found – except for *Tetrix bipunctata* – are feeding on grasses (Baur *et al.*, 2006), the higher number of individuals in areas with higher grass cover is logical. Along with Orthoptera abundance, also Orthoptera species richness was higher in a non-diverse habitat. This finding contrasts a prediction of Báldi (2008), who suggested that arthropod species richness is higher in a diverse habitat.

5.3 Distribution of Orthoptera species in the Swiss National Park

We found that altitude, vegetation height, habitat diversity, and location gave distinction to the Orthoptera communities in the SNP. *Gomphocerus sibiricus*, *Metrioptera roeselii* & *Chorthippus parallelus*, and *Chorthippus biguttulus* were the characteristic species of the different groups respectively. Those species occurred in habitats as expected from literature (Baur *et al.*, 2006). *Gomphocerus sibiricus* is common in high altitude communities and is described as a typical mountain species, while *Metrioptera roeselii*, occurring in high vegetation and low habitat diversity, is dependent on tall, dense vegetation. *Chorthippus parallelus* lives in a variety of habitats and *Chorthippus biguttulus* prefers warm and dry habitats with relatively low vegetation. There is evidence that community composition was somewhat different in the SNP in the 1920's and 1930's, when Hofmänner (1951) conducted studies on some of the grasslands we worked on. This author found neither *Chorthippus parallelus* nor *Metrioptera roeselii* on Alp Stabelchod, even though the vegetation has been described as tall grass. This might be a sampling artefact or caused by changes in vegetation composition due to an increasing ungulate density during the past eighty years. In contrast, the dominating Orthoptera species in our study on Alp Grimmels (*Chorthippus biguttulus*, *Omocestus viridulus*, *Gomphocerus sibiricus*), Margunet (*Omocestus viridulus*, *Gomphocerus sibiricus*) and on Val dal Botsch (*Omocestus viridulus*, *Gomphocerus sibiricus*, *Podisma pedestris*) were already found during the assessment in the early history of the park (Hofmänner, 1951).

6. Acknowledgements

My thank goes to my supervisor Anita Risch; to Martin Schütz, Alan Haynes, Luise Rothe and Niculin Geer for assistance in the field and in data analysis; to Janine Friedhoff, Rene Seifert and Melanie Hodel for assistance in the field and also for your encouragement and amusement; to the Swiss National Park for giving me the permission to work in the SNP and providing accommodation.

Appendix A – Orthoptera species determination check

Table A1: Comparison of Orthoptera stridulation sound records and absolute number of adult Orthoptera catches.

	Catches	Sound	Catches	Sound	Catches	Sound	Catches	Sound
	Site 1 + 3		Site 2 + 4		Site 5 + 6		Site 7 + 8	
Chorthippus biguttulus	0	absent	0	absent	0	absent	0	absent
Chorthippus parallelus	114	present	225	present	130	present	0	absent
Gomphocerippus rufus	0	absent	0	absent	14	absent	0	absent
Gomphocerus sibiricus	1	present	1	absent	8	present	23	present
Metrioptera roeselii	1	present	6	present	5	present	0	absent
Omocestus viridulus	20	present	32	present	20	present	21	present

	Catches	Sound	Catches	Sound	Catches	Sound	Catches	Sound
	Site 9 + 10		Site 11 + 12		Site 13 + 14		Site 15,16,17,18	
Chorthippus biguttulus	1	absent	87	present	41	present	0	absent
Chorthippus parallelus	0	absent	0	absent	0	absent	0	absent
Gomphocerippus rufus	0	absent	0	absent	0	absent	0	absent
Gomphocerus sibiricus	14	present	0	present	7	present	15	present
Metrioptera roeselii	0	absent	0	absent	0	absent	0	absent
Omocestus viridulus	8	present	10	present	49	present	12	present

Orthoptera voice records were compared with Orthoptera catches. *Gomphocerippus rufus* grasshoppers had been caught at Stabelchod Dadaint (sites 5&6) but no sound could be recorded. According to Roesti & Keist (2009) the stridulation sound of *Gomphocerippus rufus* is low and is performed in irregular intervals. Probably that's the reason why it could not be recorded. According to Baur *et al.* (2006) *Chorthippus biguttulus* belongs to a group of grasshoppers which can only be distinguished by the stridulation sound of male grasshoppers. In the records only the sound of *Chorthippus biguttulus* could be heard. Therefore we can assume that it is the only one grasshopper species representing this group at the sampling sites. Species *Bohemanella frigida*, *Podisma pedestris* and *Tetrix bipunctata* don't produce any stridulation sound (Baur *et al.*, 2006).

Appendix B – Data used for analysis

Table B1: Orthoptera counts 2010. Counts in open quadrates in 0.25m^2.

Orthoptera counts 2010

Table B1 continued: Orthoptera counts 2010

Quadrate area: 0.25 m^2

Method 1 = Each of the two researchers counts all Orthoptera in the quadrate. Average per quadrate gives the total number of Orthoptera per quadrate.

Method 2 = Each researcher counts all Orthoptera in half of the quadrate. Sum per quadrate gives the total number of Orthoptera per quadrate.

Measurement	Fence	Transect	Number of Orthopter (1)					Number of Orthoptera (2)					
			Quadrate 1	Quadrate 2	Quadrate 3	Quadrate 4	Quadrate 5	Quadrate 1	Quadrate 2	Quadrate 3	Quadrate 4	Quadrate 5
